A 69-year-old woman was diagnosed right breast cancer which was a stage III invasive ductal breast carcinoma with high proliferative activity (Ki-67 expression: 30%) positively-stained cell), positive hormone receptor (androgen receptor) and HER2 overexpressed. Echocardiography before initial chemotherapy showed normal left ventricular (LV) size and function. After the initial echocardiographic study, the patient was given 4 cycles of epirubicin and cyclophosphamide, followed by 3 cycles of trasuzumab and paclitaxel as neoadjuvant chemotherapy. The patient was performed surgical resection of right breast cancer at 6 months later from initial chemotherapy. After initial chemotherapy, global longitudinal strain (GLS) seemed to decrease from the baseline values, however LV ejection fraction (EF) did not change within normal limit during 15 months follow-up. After 15 months from initial chemotherapy, although serum B-type natriuretic peptide is 30pg/ml and high sensitive troponin I is <5mg/dl, she had mild exertional breathlessness. Transthoracic echocardiography after 15 months from initial chemotherapy showed decreased LVEF of 33% (FIGURE), then she was diagnosed chemotherapy-related cardiac dysfunction (CTCRD). We stopped chemotherapy, and patient was provided heart failure pharmacological treatment with enalapril 2.5mg, carvedilol 2.5mg, and azosemide 15mg/day (SUPPLEMENT 1). With a slow pharmacological up-titration, LVEF and GLS had normalized. This case shows two important insights. The first is that importance of regular sequential follow-up examination. We can find the tiny change of LV systolic dysfunction by performing regular follow-up examinations. CTRCD is occurred in 6-9% of patients with chemotherapy within 12 months from the last administration [1]. However, many literatures reported that CTRCD also occurred in remote phase [2]. We

should perform sequential echocardiographic examination, cardiac magnetic resonance

- 1 imaging or multigated acquisition scan because CTRCD is defined by the value of
- 2 LVEF. The second is to confirm that we can detect the early change of LV systolic
- 3 dysfunction due to chemotherapy by GLS rather than LVEF. Previous literature reported
- 4 that the patients with 11% decreased of ΔGLS after chemotherapy had more
- 5 development of CTRCD [3]. SUPPLEMENT 1 shows the measurements of LVEF and
- 6 GLS every 3 months during follow-up. The decrease of Δ GLS of 14% at follow-up
- 7 study 3 months later from initial chemotherapy may indicate the early impairment of LV
- 8 myocardium. According to our case, it is important to evaluate regularly cardiac systolic
- 9 function after chemotherapy, and GLS is more useful than conventional values such as
- 10 LVEF to detect early stage of myocardial impairment as pre-stage of CTRCD.

1	Funding
2	None.
3	Compliance with ethical standards, Human rights statement
4	All procedures followed were in accordance with the ethical standards of the
5	responsible committee on human experimentation (institutional and national) and with
6	the Helsinki Declaration of 1964 and later revisions.
7	Informed consent
8	Informed consent was obtained from the patient for being included in this case report.
9	Conflict of interest
10	Yoshihito Saijo, Kenya Kusunose, Nao Yamada, Hirotsugu Yamada, Susumu Nishio,
11	Yukina Hirata, and Masataka Sata declare that they have no conflict of interest.

FIGURE LEGENDS

FIGURE.

- 3 This is the time course figure about global longitudinal strain (GLS) and left ventricular
- 4 ejection function (LVEF): Upper figures show the polar maps by using speckle tracking
- 5 method and lower figure shows time courses of Δ GLS and Δ LVEF. The decrease of
- 6 ΔGLS of 14% at follow-up study 3 months later from initial chemotherapy was shown
- 7 (arrow).

SUPPLEMENT 1.

10 This is the flow diagram of chemotherapy and cardiac protection therapy.
